ROUTING INFORMATION PROTOCOL

Overview

RIP (**Routing Information Protocol**) is one of the oldest distance vector protocol routing protocols, invented in the 1980s. It uses the hop count (the number of routers between the source and destination network) as the metric and is very simple to configure. Two versions of the protocols were developed:

- RIP version 1 supports only classful routing and doesn't send subnet masks in routing updates. Uses broadcasts for updates.
- RIP version 2 supports classless routing and sends subnet masks in routing updates. This version uses the multicast address of 224.0.0.9 to send routing updates.

RIP has a default administrative distance of 120. It sends the entire routing table
every 30 seconds , which can consume a lot of network bandwidth. The hop count
limit is 15 . Any route with a higher hop count will be marked as unreachable.

HOH DJ. G0/0 R3 S0/0/0 S0/0/1 I have a route to I have a route to 172.16.3.0/24, metric 1. 172.16.3.0/24, metric 2. I'll use the route out S0/0/0, because it has the lower metric. S0/0/0 S0/0/1 172.16.6.252 S0/0/1 S0/0/0 G0/1 G0/0 172.16.2.252 172.16.1.0/24 172.16.3.0/24 **R1 IP Routing Table** I have a route to Subnet Metric Out Int. Next-Hop

172.16.3.0/24, metric 1.
